

Technical Overview - Sprint 1

Short summary of what's actually live in this deployment, what's deliberately left out, and why for the sprint 1 playback.

What's live

Layer	Technology	Notes
Frontend	Next.js 16 (App Router), deployed on Vercel	Free/Hobby tier. Server Components by default; auth-protected routes render behind <code>requireAuth()</code> .
Auth	Firebase Authentication	Email/password (with email verification required before sign-in) and Google OAuth. Password reset is implemented. Session is bridged to the server via a signed cookie (<code>/api/auth/session</code>), checked on every protected page load.
Database	Cloud Firestore (Native mode, free Spark plan)	One collection live so far: <code>users/{uid}</code> — profile doc created on first sign-in, readable/writable only by its owner (see <code>firebase/firestore.rules</code>).
Hosting/CI	GitHub Actions → Vercel	Lint, typecheck, and unit tests run on every PR. <code>pnpm audit --audit-level=high</code> also runs in CI and blocks merges on high/critical vulnerabilities.

What's excluded, and why

Feature	Status	Reason
Firebase Cloud Storage	Not used	Requires the paid Blaze plan. Any file/photo needs (e.g. team member photos) use static assets under <code>public/</code> for now instead of user-uploaded storage.
Cloud Functions (backend/Express API)	Scaffolded, not deployed	Also requires Blaze. The backend/ package exists in the repo and is fully testable locally (mocked Firebase Admin, no real calls), but there is no live backend API behind this deployment. All data access so far goes through Firestore directly from the Next.js server, not through custom Cloud Functions endpoints.

Both exclusions are cost decisions, not technical blockers, the code paths are ready to extend once/if the project moves to a paid plan.

Features implemented for this playback

- Sign-up, sign-in, sign-out, Google sign-in, and password reset, all working end-to-end, with clear error states (invalid credentials, unverified email, email already in use, rate-limiting on reset)
- Dashboard: next-race hero, driver standings, circuit overview, personal ticket card, available upgrades, upcoming races, and next-session list
- Team page (auth-protected), listing team members

All dashboard/team content is currently **static placeholder data** (see features/*/data.ts), each explicitly marked with a TODO pointing at the Firestore collection it will eventually read from. No dynamic data pipeline exists yet beyond the users collection.

Demo-readiness checklist

To be worked through and checked off by hand before the playback — this can't be verified from a local dev environment alone, since it depends on the live Vercel deployment and the production Firebase project:

- [] pnpm run lint && pnpm run typecheck && pnpm run test:all pass locally on the branch being deployed
- [] pnpm audit --audit-level=high returns clean (see docs/SECURITY.md for the current known-vulnerability overrides)
- [] Vercel production deployment is on the latest merged commit, not a stale preview
- [] All required env vars are set in Vercel project settings (not just locally) — cross-check against docs/ENV-VARS.md
- [] Firestore rules deployed to the production project (firebase deploy --only firestore:rules) and confirmed live in Firebase Console, not just present locally
- [] On the live URL: sign-up → email verification → sign-in → sign-out → Google sign-in → password reset all complete with no console errors
- [] Dashboard and Team pages load without errors while signed in
- [] Sign-out and an unauthenticated visit to /dashboard correctly redirects to /auth/signin

Known limitations to mention if asked

- No real race/ticket/standings data yet, everything shown is placeholder content, not connected to a live data source
- No file upload capability (Storage excluded)
- No custom backend API in production (Cloud Functions excluded)
